

Reset95 · Ad-Tech Marketplace (Flutter + Firebase)

App ID	com.nammaempire.nammasign	Version	1.0.0 (build 1)
Platform	Android (compileSdk 36)	Date	6 August 2026

Executive summary

The Android app is built on a clean, professional foundation — feature-first architecture with Riverpod, a full Firebase backend (Auth, Firestore, Storage, Cloud Functions, FCM), crash reporting and analytics, properly guarded release signing, and in-app legal pages. Login works on debug builds and the recent Reset95 rebrand (name + icons) is in place. It is **not yet ready for a public Play Store launch**: one critical item currently blocks OTP on release builds, a payment decision must be made, and several hardening and store-compliance items remain. With the sequence on the final page, a realistic path to an internal test build is short, and to public launch is a few focused days of work.

12 Ready	2 Critical	3 High	7 Store / Medium
-------------	---------------	-----------	---------------------

What's ready ✓ done

Area	Detail
Architecture	Clean feature-first structure (domain / data / presentation), Riverpod state, GoRouter with auth-aware redirects. Maintainable and testable.
Authentication	Firebase Phone OTP (Google / Apple scaffolded). Confirmed working on debug builds.
Backend	Cloud Firestore + Storage + Cloud Functions + FCM, with a documented data model (FIREBASE_ARCHITECTURE.md).
Monitoring	Crashlytics + Analytics wired in main.dart with release-only collection and global error handlers.
Release signing	Configured via git-ignored key.properties + real upload keystore; build aborts loudly rather than shipping a debug-signed release.
Identifiers	applicationId & namespace = com.nammaempire.nammasign — consistent, and matches the Firebase Android app + registered debug SHA.
Permissions	Minimal and correct: INTERNET, POST_NOTIFICATIONS. File uploads use the system document picker (no broad media permissions needed).
Security rules	Firestore + Storage rules are authentication-gated; anonymous waitlist writes were closed to signed-in users only.
Legal pages	In-app Privacy Policy + Terms (DPDPA-aware), linked from Profile.
Branding	Rebranded to Reset95 — app name, launcher icon, and splash lockup updated.
Recent features	Multi-photo ad-creative upload (up to 5) and corporate-details gating for individual users booking as corporate.
Tests (partial)	Unit tests for GST/discount pricing math, form validators, and string helpers.

Critical ■ must fix before real users

#	Item	Why it matters & action
1	Release OTP is broken	The built APK is signed with the release keystore whose SHA-1/SHA-256 are NOT registered in Firebase, so phone verification fails (“missing a valid app identifier”). Debug builds work because the debug SHA is registered. Action: run <code>gradlew signingReport</code> , add the release SHA-1 & SHA-256 to the <code>com.nammaempire.nammasign</code> app in Firebase Console.
2	Payment not enforced	“Pay” sends a booking straight to <code>pending_review</code> (<code>paid = false</code>) while the UI still reads “Powered by Razorpay · 256-bit encryption.” For a paid marketplace this is a trust/compliance risk. Action: either wire the Razorpay Cloud Functions (already specced) or soften the copy and treat payment as manual/offline for launch.

High ■ harden before scale

#	Item	Why it matters & action
3	Firebase App Check missing	No <code>firebase_app_check</code> dependency or activation. Leaves Firestore / Storage / Functions open to abuse and weakens phone-auth attestation. Action: add the package, activate with the Play Integrity provider, register in console, enforce after monitoring.
4	R8 shrinking / obfuscation OFF	<code>isMinifyEnabled</code> and <code>isShrinkResources</code> are false — turned off after a release crash caused by missing keep rules. Ships a larger, un-obfuscated APK. Action: add ProGuard keep rules (Firebase, Flutter, models), re-enable R8, and smoke-test the release build.
5	Thin test coverage	Only a few unit tests exist. No Firestore security-rules tests, no widget/integration smoke tests, no Cloud Functions tests. Action: add rules tests (emulator) + key-flow smoke tests before scaling users.

Store & configuration ■ required to publish

#	Item	Why it matters & action
6	Play Console not set up	Create the app, an internal-testing track, and upload a signed AAB.
7	Play App Signing SHA	When published, Google re-signs the app with its own key. Add Google’s app-signing SHA-1/256 (Play Console → App integrity) to Firebase, or OTP breaks for Play installs.
8	Data Safety + privacy URL	Play requires a public Privacy Policy URL and a completed Data Safety form. In-app pages exist but need hosting + the declaration.
9	Account/data deletion path	Play requires an in-app deletion flow AND a public web URL. A deletion Cloud Function exists — expose it and publish the URL.
10	targetSdk compliance	Confirm <code>targetSdk</code> meets Play’s current minimum (35). Currently inherited from the Flutter default — verify before upload.
11	Adaptive launcher icon	Only legacy <code>mipmap</code> PNGs are present. Add an adaptive foreground/background (<code>mipmap-anydpi-v26</code>) for crisp masked icons on Android 8+.
12	Version management	Bump <code>versionCode</code> / <code>versionName</code> on every release (currently 1.0.0+1).

Polish & cleanup ■ nice to have

#	Item	Why it matters & action
13	google-services.json cleanup	Contains stale/typo package entries (com.example..., com.nammaempire.nammsign). Harmless but should be cleaned.
14	Leftover package folder	An empty com/reset95/app Kotlin folder remains from the rebrand experiment — remove it.
15	Docs still say NammaSign	README / project docs describe the old brand and phase state. Update to Reset95.
16	Secrets hygiene	Keystore password is plain text in key.properties (git-ignored — keep it so). Rotate if ever exposed.

Recommended sequence to production

1	Register the release SHA-1 & SHA-256 in Firebase → OTP works on the built APK (unblocks everything).
2	Decide payments : integrate Razorpay, or soften the copy and run a manual/offline flow for launch.
3	Add App Check ; re-enable R8 with keep rules and smoke-test the release build.
4	Play Console setup: internal-testing track, signed AAB, add the Play App Signing SHA to Firebase, complete Data Safety + deletion URL.
5	Expand tests ; run an internal test with 10–30 users; watch Crashlytics for crash-free rate.
6	Finalise store listing (screenshots, feature graphic, adaptive icon) and docs → staged production rollout.

Assessment based on the current project state on 6 August 2026. iOS is tracked separately and is not covered here. “Ready” means implemented in the codebase; some items still require a one-time Firebase Console or Play Console action outside the app.
