

Reset95 · com.nammaempire.nammasign

App ID	com.nammaempire.nammasign	Version	1.0.0 (build 1)
--------	---------------------------	---------	-----------------

Already in place

Architecture, Firebase backend (Auth/Firestore/Storage/Functions/FCM), Crashlytics + Analytics, guarded release signing, minimal permissions, auth-gated security rules, in-app legal pages, the Reset95 rebrand (name + icon), and unit tests for pricing/validators are all done. Login works on debug builds.

2 Critical	3 High	7 Store/Med	4 Polish
---------------	-----------	----------------	-------------

Critical ■ must fix before real users

#	Item	Why it matters & action
1	Release OTP broken	The built APK is signed with the release keystore whose SHA-1/SHA-256 are not registered in Firebase, so phone verification fails. Debug works because its SHA is registered. Action: add the release SHA-1 & SHA-256 (from gradlew signingReport) to the Firebase Android app.
2	Payment not enforced	Bookings go straight to pending_review (paid=false) while the UI still says “Powered by Razorpay · 256-bit encryption.” Action: integrate Razorpay (Cloud Functions are spec'ed) or soften the copy for a manual/offline flow.

High ■ harden before scale

#	Item	Why it matters & action
3	Firebase App Check missing	No App Check dependency. Leaves Firestore/Storage/Functions open to abuse. Action: add the package, activate with Play Integrity provider, enforce after monitoring.
4	R8 shrink/obfuscation OFF	Disabled after a release crash (missing keep rules). Ships a larger, un-obfuscated APK. Action: add ProGuard keep rules, re-enable R8, smoke-test release.
5	Thin test coverage	Only a few unit tests. Action: add Firestore rules tests + widget/flow smoke tests before scaling.

Store & configuration ■ required to publish

#	Item	Why it matters & action
6	Play Console setup	Create the app + internal-testing track; upload a signed AAB.
7	Play App Signing SHA	Google re-signs on publish — add its app-signing SHA-1/256 to Firebase or OTP breaks for Play installs.
8	Data Safety + privacy URL	Public Privacy Policy URL + completed Data Safety form (in-app pages exist; need hosting).

#	Item	Why it matters & action
9	Account/data deletion	Play needs an in-app deletion flow AND a public web URL (deletion function exists — expose + publish URL).
10	targetSdk compliance	Confirm targetSdk meets Play's current minimum (35).
11	Adaptive launcher icon	Add adaptive foreground/background (mipmap-anydpi-v26); only legacy PNGs exist.
12	Version management	Bump versionCode/versionName per release (currently 1.0.0+1).

Polish & cleanup ■ nice to have

#	Item	Why it matters & action
13	google-services.json cleanup	Remove stale/typo package entries (com.example..., nammsign).
14	Leftover Kotlin folder	Delete the empty com/reset95/app folder from the rebrand experiment.
15	Docs say NammaSign	Update README/docs to Reset95.
16	Secrets hygiene	Keystore password is plain text in key.properties (git-ignored — keep it so); rotate if exposed.

Recommended sequence

1	Register the release SHA-1 & SHA-256 in Firebase → OTP works on the built APK.
2	Decide payments: integrate Razorpay or soften the copy for a manual flow.
3	Add App Check; re-enable R8 with keep rules and smoke-test the release.
4	Play Console setup: signed AAB, add Play App-Signing SHA to Firebase, Data Safety + deletion URL.
5	Expand tests; internal test with 10–30 users; watch Crashlytics.
6	Store listing (screenshots, feature graphic, adaptive icon) + docs → staged rollout.

State as of 6 August 2026. "Already in place" = implemented in the codebase; several remaining items require a one-time console/portal action (Firebase, Play Console, Apple Developer) outside the app.
